ABSTRACT

In a front part inside a seat cushion [[(1)]] are arranged a catching member [[(15)]] extending in a widthwise direction of the seat cushion [[(1)]] and movable up and down, and inertial force transmission means for moving the catching member [[(15)]] upward by the inertial force that acts on an inertial mass [[(17)]] at the time of rapid deceleration. When a passenger sits on the seat cushion [[(1)]], the catching member [[(15)]] moves down so as not to deteriorate the seat comfort, and at the time of rapid deceleration, the catching member [[(15)]] moves up and stops the passenger's hips [[(24)]] from moving forward. Thus it is reliably prevented that the passenger moves forward, without deteriorating the seat comfort, and the design is simple, lightweight, and low-cost.
